Abstract
Steganography can be defined as the science of private communication while steganalysis is the science of detection of embedded messages in digital media with the use of steganography (Each of steganography and steganalysis are under much interest from media and law enforcement entities). Blind steganalysis had the attempt of differentiating steganographic images from cover images without knowing the method of steganography.

Popular data-sets are common in various areas like image processing, artificial intelligent, and security which allow the researchers to validate their approaches. INRIA dataset is one type of image dataset which include Holiday, Copydays and BIGANN evaluation datasets. This paper presents study on number of researches using INRIA dataset for image/ information retrieval and especially blind image steganalysis. All these works depends on statistical properties of image. No one use machine learning tools like deep learning especially convolution neural network to detect attack in image using INRIA dataset. [DOI: 10.22401/ANJS.21.4.13]

Keywords: image steganalysis, INRIA, image retrieval, image detection.

Introduction
Steganography is a method of hiding secret information into seemingly innocent cover medium like a digital image, video, audio and text in such a way that existence of message is not visible [1]. It is derived from Greek words "Steganos" and "Graphy" which mean hidden and writing. The cover file with secret message hidden in it is referred as "stego" file [2].

The modern steganography algorithms are extremely secure which makes it difficult to visually detect any changes in the stego file. However, statistical properties of the cover images are modified through these steganography algorithms, which can be exploited to detect steganography. This process of identifying these statistical changes is known as steganalysis which is an extremely challenging task and demands in-depth computational analysis [3].

The significance of steganalysis approaches which are capable of a reliable detection of the existence of embedded data in images increases continuously. Steganalysis is utilized in different areas, such as forensics, cyber warfare, tracking criminal activities via the internet and obtaining evidence concerning investigations specifically in anti-social elements cases [4, 5].

Image steganalysis algorithms are basically of two types, which are: Specific and Generic [6].

Specific
This method is a category of image steganalysis approaches which are highly dependent on the underlying steganography method that has been utilized and are of a high rate of success in the detection of the existence of the hidden message if the message is embedded using the method for which the approaches are intended for.

Generic
It is a category of image steganalysis approaches which are not dependent on the underlying steganographic method that has been utilized for message embedding and guarantees good results in the detection of the existence of a hidden message that has been embedded with the use of new and/or unconventional steganography methods.

Image steganalysis approaches under both those classes are typically designed for the detection of the existence of a hidden message and the decoding of the same is considered complementary not mandatory [6].

Blind steganalysis is comprised of two processes Feature Extraction and
Classification [7]. During the training phase of any blind steganalysis, a set of features of each of Stego and Cover images are passed to a statistical classifier. The learning classifier then develops a model that maps the training set to one of the predefined class labels. In the stage of testing, the same group of properties of unknown images is fed as input to the trained classifier for deciding if these images contain any secret messages and accordingly discriminate.

**INRIA Dataset**

Many datasets and protocols of various sizes become standard for comparison of the image, video, text and, etc. for evaluation. Popular data-sets are common in various areas like Image Processing, AI, Cyber Security, and so on. Those data-sets which are publicly available give the ability to researchers for validating, benchmarking, and reproducing approaches which have been previously reported or presented, thereby emphasizing transparency and integrity of academic researches. Image datasets are a highly important part of image classification researches. They are needed for the learning of visual image models and assessing the efficiency of classification and detection [8].

In 2008 [10], INRIA data-sets were produced in the context of the ANR RAFFUT project. Grouping two companies INRIA (for contacting: “Herve Jegou”) and the Advestigo lead to support The “Agence Nationale de la Recherche”. In their work these enhances new approaches for large scale image search. Standard approaches are built based on the bag-of-properties image representation. Initially, they analyze bag-of-Properties in the structure of approximate nearest neighbor searching, which proves the sub-optimality of this type of representation to match descriptors and lead to deriving a more accurate representing according to [9]:

1) **Hamming Embedding** (HE): offers binary signatures refining the matching according visual words.

2) **Weak Geometric Consistency constraints** (WGC): filters matching descriptors which are inconsistent according to angle and scale.

Combining of both two above in inverted file and are sufficiently utilized for every image, even with huge data-sets. Experiments that have been done on a data-set of million images showed great deal of enhancement because of the binary signature and the weak geometrical consistency constraints in addition to their sufficiency. Estimating the entire geometrical transforming, in other words, a reranking stage on a small set of images is complementary to the weak geometrical consistency constraints and offers additionally improving the precision [9].

They propose in the following a binary signature generation procedure that distinguish between Off-line learning procedure, which is performed on a learning dataset and generates a set of fixed values, and Binary signature computation itself. The offline procedure is performed as follows: [9]

1. **Random matrix generation:**
   A $d_b \times d$ orthogonal projection matrix $P$ is generated. They randomly draw a matrix of Gaussian values and apply a QR factorization to it. The first $db$ rows of the orthogonal matrix obtained by this decomposition form the matrix $P$.

2. **Descriptor projection and assignment:**
   A large set of descriptors $x_i$ from an independent dataset is projected using $P$. These descriptors ($z_{i1}, ..., z_{ib}$) are assigned to their closest centroid $q(x_i)$.

3. **Median values of projected descriptors:**
   For each centroid $I$ and each projected component
   
   $h = 1, \ldots, db,$

   they compute the median value $\tau_{1h}$ of the set $\{z_{ih} | q(x_i) = 1\}$ that corresponds to the descriptors assigned to the cell $I$. The fixed projection matrix $P$ and $k \times db$ median values $\tau_{l1}$ are used to perform the HE of a given descriptor $x$ by:

   1. Assigning $x$ to its closest centroid, resulting in $q(x)$.
   2. Projecting $x$ using $P$, which produces a vector
      $z = P x = (z_1, \ldots, z_{db})$.
   3. Computing the signature
      $b(x) = (b_1(x), \ldots, b_{db} (x))$ as
      
      $$b_i(z) = \begin{cases} 1 & \text{if } z_i > \tau_{q(x)i}, \\ 0 & \text{otherwise}. \end{cases}$$

| Holidays | • Remaining ones have been taken on deliberately for testing how robust they are to different types of transformations such as: rotations, view-point and variations in illumination, and blurring.  
• Personal holiday images of INRIA researchers of about 1491 images.  
• It includes 500 image sets (i.e. queries), every one of which denotes a separate scene (for the sake of incorporating diversity) and 991 corresponding relevant images.  
• It so many scene categories (man-made, water and fire effects, natural, and so on) and high resolution.  
• Number of generated descriptors: 4455091 SIFT descriptors of 128 dimensional.  
• First image of every one of the groups is the query image and the precise retrieving outputs are the rest of the images of the set. | • Descriptors with size equal to (526MB).  
• Images: jpg1.tar.gz and jpg2.tar.gz (1.1GB and 1.6 GB).  
• Visual dictionaries (100, 200, 500, 1K, 2K, 5K, 10K, 20K, 50K, 100K and 200K visual words, 144MB) learned on Flickr60K.  
• Descriptors of Flickr60K (independent dataset, 636MB).  
• Pre-computed features for one million images, stored in 1000 archives of 1000 feature files each (235GB in total). |
| Copydays | • Every one of the images has undergone 3 types of artificial attacks, which are: JPEG, cropping and "strong".  
• It’s a group of images that is entirely made up of personal holidays’ images.  
• It’s assessed via merging the original images in a large data-base of images because of its small image.  
• It’s utilized for the evaluation of the indexing algorithms behavior for most widely used image copies. | • Cropped images, from 10% to 80% of the image surface removed, 2.0GB).  
• Original images (208MB).  
• 229 Strongly attacked images (60MB), print and scan, blur, paint.  
• Scale+JPEG attacked images (77MB), scale: 1/16 (pixels), JPEG quality factors: 75, 50, 30, 20, 15, 10, 8, 5, 3. |
| BIGANN evaluation | • Specifically, there is a huge group of a billion vectors, which is the largest group available for evaluating Artificial Neural Network approaches.  
• It offers numerous evaluation groups for the evaluation of the quality of approximate nearest neighbors search approach on various data types and different sizes of databases.  
• Every one of which includes three sub-sets of vectors:  
  • Query vectors  
  • Base vectors: vectors where the search is done.  
  • Learning vectors: detect parameters that are involved in a specific approach. | • ANN_SIFT1M: sif.tar.gz, (161MB)  
• ANN_SIFT10K:siftsmall.tar.gz, (5.1MB).  
• ANN_GIST1M: gist.tar.gz, (2.6GB)  
• ANN_SIFT1B: Base set, (92 GB)  
  • Learning set, (9.1 GB)  
  • Query set, (964 KB)  
  • Groundtruth, (512 MB) |

• Results indicated that the regular dense detector is inferior to other approaches in the majority of cases, resulting in improving the standard in comparable setups on standard retrieving and fined-grained benchmarks.  
• Recent image retrieval and fine-grained classification indicators were evaluated for dissimilar approaches.  
• Existing blob and super pixel extracting approaches performed with high degree of precision in the case where the patches are obtained along the edges and not surrounding the found areas. |
| [14, 2016]  | • Proposed an extensive research systematically evaluating the Fisher Vectors (FVs) and Convolutional NNs (CNNs) for instant image retrieval.  
• First part performs a comparison the performances of Fisher Vectors and Convolutional NNs on numerous publicly available datasets and for several criteria. (None of the descriptors are systematically more efficient than the other and that efficiency gains are typically be obtained with the use of a combination of both types.  
• Second part is focused on the effect of geometry transformations.  
• Specifically useful and implementable guide-lines to any person who is looking for standard global descriptors which are optimal for their specific image instance retrieving task.  
• The efficiency of Convolutional Neural Network could rapidly degrade with specific transformations and suggest some means of incorporating the necessary invariances in the pipeline of the Convolutional Neural Network. |
| [15, 2016]  | • First, the task is developing a CNN model which is trainable in an end-to-end way in a direct manner for the place identification process.  
• NetVLAD, which is a new generalized layer of VLAD, and takes its inspiration by the “Vector of Locally Aggregated Descriptors” image representation typically utilized in retrieving images.  
• Layer is readily pluggable into any Convolutional Neural Network model and amenable to training by back-propagation approach.  
• Second, the process is developing a training process, according to a new weakly supervised ranking loss, for the sake of learning parameters of the model in end-to-end way from images that depict same places over time downloaded from “Google Street View Time Machine”.  
• This model is greatly superior to the non-learnt image representation and off-the-shelf Convolutional Neural Network descriptors on 2 challenging place identification indicator, and enhances over current standard compact image representations on standard image retrieving representations. |

</thead>
</table>
| [16, 2017]  | • Gradient Boost Ensemble Classification (GBEC) technique is proposed to solve problem of non-effect for achieving higher precision and recall for video retrieval.  
• It first takes video query as input.  
• It used Independent Component Analysis Model for extracting the visual properties like the shape, color, texture in videos for efficient classification.  
• After extracting visual features, GBEC approach applied Gradient Boost Ensemble Classifier in order for classifying the videos in a certain data-set as similar or dissimilar based on video query which resulted in enhanced classification precision.  
• Finally, the classified similar videos’ are retrieved on the basis of the video query which in turn helps for increasing video retrieval accuracy and recall with the minimal amount of time.  
• The performance of GBEC approach is measured in according to metrics such as classification precision, time complexity, Precision and recall with aid of three datasets in comparison with the state-of-the-art works. |
| [17, 2017]  | • It alleviates the restrictive compactness needs of hash codes via extending those codes into a 2-level hierarchic coding strategy.  
• It generates sufficient multi-level hashing codes for image retrieving, on the base of the deep Siamese CNNs (DSCNN).  
• At execution time, adopting an attention-based approach for selecting some of its most important bits special for every one of the query images for retrieval rather than the use of full hash codes of the 1st level. |
• It is designed by enhancing the efficiency of digital multi-media data retrieving with the use of machine learning classifier method.  
• At first, it takes video query as input and applies “Kernel-principal component analysis” (Kernel-PCA) for the extraction of the visual properties like shape, colour, and texture in videos.  
• Then, BALC approach uses “Bootstrap Aggregation with Support Vector Machine” (BA-SVM) Classifier for the classification of videos in a certain data-set as relevant or irrelevant with the use of video query with enhanced classification precision.  
• Finally, the BALC approach performs retrieval of the classified relevant videos’ according to the query.  
• This procedure helps BALC approach in improving video retrieval recall and accuracy in the minimal amount of time.  
• The BALC approach works on conducting experiments on parameters like the precision of the classification, time complexity, accuracy and recall with the use of 3 data-sets with higher classification precision and minimal amount of time complexity for multi-media data retrieving in comparison with the standard works. |
| [19, 2018]  | • Proposed an innovative model for achieving competitive retrieval efficiency.  
• Present different masking approaches, such as SIFT-mask, SUMmask, and MAX-mask, for selecting a representative sub-set of local convolutional properties and eliminate many redundant properties from a feature map. They are effectively for addressing the burstiness problem and enhance the accuracy of retrieval.  
• Proposed employing recent embedding and aggregating approaches for further enhancement of property discriminability.  
• Include a hashing module to produce compact binary image representations which are effective for the retrieval. |

</table>
Use two base architectures which are extended with Max pooling (fmax) and our NetVLAD (fV LAD) layers: AlexNet and VGG-16; both are cropped at the last convolutional layer (conv5), before ReLU. For NetVLAD we use $K = 64$ resulting in 16k and 32k-D image representations for the two base architectures, respectively.

Comparison of our methods versus off-the-shelf networks and state-of-the-art. The base CNN architecture is denoted in brackets: (A)lexNet and (V)GG-16. Trained representations (red and magenta for AlexNet and VGG-16) outperform by a large margin offthe-shelf ones (blue, cyan, green for AlexNet, Places205, VGG-16), fV LAD (-o-) works better than fmax (-x-), and our fV LAD+whitening (-*-) representation based on VGG-16 sets the state-of-the-art on all datasets. [80] only evaluated on Tokyo 24/7 as the method relies on depth data not available in other datasets.

**Comparison with state-of-the-art.** Figure above also shows that our trained fV LAD representation with whitening based on VGG-16 (magenta -...) convincingly outperforms Root-SIFT+VLAD+whitening, as well as the method of Torii et al. and therefore sets the state-of-the-art for compact descriptors on all benchmarks. Note that these are strong baselines that outperform most off-the-shelf CNN descriptors on the place recognition task.

**VLAD versus Max.** By comparing fV LAD (-o-) methods with their corresponding fmax (-x-) counterparts it is clear that VLAD pooling is much better than Max pooling for both off-the-shelf and trained representations.

NetVLAD performance decreases gracefully with dimensionality: 128-D NetVLAD performs similarly to 512-D . Max (42.9% vs 38.4% recall@1 on Tokyo 24/7), resulting in four times more compact representation for the same performance. Furthermore, NetVLAD+whitening outperforms Max pooling convincingly when reduced to the same dimensionality (60%).

             • Trade-off between block number and block size through test image.  
             • Suggest using overlap blocks to make the performance of steganalysis better.  
             • Fisher linear discriminant classifier and the logistic classifier outperform linear Bayes classifier by a huge difference. |
| [25,2016]   | • Discovering capability regarding steganography algorithm was utilized for sample stego-image via designing a multi classifier.  
             • Kind of classification was used for the steganalysis of image’s smaller blocks. Since the plain images mainly have heterogeneous regions. At first, main image was decomposed to smaller and similar blocks.  
             • After that, those similar blocks were placed in same class.  
             • Thus, a number of various classes were obtained, and for each class of them, suitable classifier was recognized.  
             • This method led to making decisions for the purpose of recognizing and identifying the status of image blocks which were either stego or cover and recognizing steganography algorithm utilized in stego-images. |
|             | • It offers an innovative host-based approach for discriminating and identifying Stegobot profiles.  
             • Identify Stegobot network traffic that is inherently distinct from the legitimate multimedia social network traffic.  
             • Performance distinct social networks dataset with distinct evaluation metrics.  
             • Exploring botnet hidden communication structure is done with the help of proposed multiple aspects of multimedia characteristics.  
             • Profiles of stegobot simulate authentic users and jeopardize others in the social network.  
             • Process of detecting stegobot communication and bot profiles is very difficult when utilizing only one view features thus here a work of multi feature method is utilized.  
             • Furthermore, this study tries to offer help to forensic analysts and experts in network security field to grasp the idea of Stegobot communication and the significant profiles in malicious networks. |

**Conclusion**

Different techniques have been appeared in the field of information hiding for protect data especially image while transfer through communication.

This study outlines the problem of detecting attacks from embedding information in image. INRIA image dataset consists of scene categories (man-made, water and fire effects, natural, and so on) with high resolution which can be used for image retrieval extract descriptors and search neighbor. It reviews numbers of works for blind image steganalysis which used INRIA dataset.
